Nitrogen cycling in reef-building corals is a function of all holobiont members. Control of nitrogen cycling may stabilize holobiont functioning under oligotrophic and eutrophic conditions.

## **Nitrogen cycling in corals: the key to understanding**

The "nitrogen cycle" is the biogeochemical cycle by which nitrogen is converted into multiple chemical forms as it circulates among atmosphere, terrestrial, and marine ecosystems. The conversion of nitrogen can be carried out through both biological and physical processes. Important processes in the nitrogen cycle include fixation, ammonification, nitrification, and denitrification.

California Agriculture - Current issue and featured articles. Alternaria late blight (ALB), caused mainly by the fungal pathogen *Alternaria alternata*, is an important pistachio disease that causes severe tree defoliation and fruit shell staining. Its control relies on multiple fungicide sprays, including carboxamide fungicides.

Nitrogen fixation is a process by which nitrogen in the Earth's atmosphere is converted into ammonia (NH<sub>3</sub>) or related nitrogenous compounds. Atmospheric nitrogen, which is molecular dinitrogen (N<sub>2</sub>), is relatively nonreactive and is metabolically useless to all but a few microorganisms. The fixation process converts N<sub>2</sub> into ammonia, which is metabolized by most organisms.

Most studies on plant nutrition tend to focus on the topsoil (plough layer) and frequently neglect subsoil processes. However, cereal roots can potentially acquire nutrients including organic and inorganic nitrogen (N) from deep in the soil profile.
